Technical introduction

The Phönix change over valve is a three-way globe valve that is useful in all locations where a shutdown cannot be tolerated, either for safety reasons or due to plant and production conditions. With its globe valve style design the phönix valve offers advantages over conventional three-way ball or plug valves like bubble tight conical metal seating or an optional bellows stem seal. These and other features make the valve extremely useful for a wide range of applications.

Used as diverter valve (fig. 1) change over valves enable a quick and safe switch between product lines, safety systems, or to start-up tanks for solvent flushing. To accommodate different piping situations the Phönix Valve allows the rotation of the elbows to any 90° angle.

fig.1

Pressurized systems should always be equipped with dual safety relief devices to allow frequent maintenance without disabling the overpressure protection. In many cases safety relief valves are used and are subject to frequent resetting due to operating conditions. Phönix change over valves (fig. 2) offer the most convenient and ideal solution considering the short time of operation to switch between the safety relief valve in service and the standby valve. An important safety aspect is addressed due to the fact that the valve does not allow isolating both safety relief devices at the same time. Eliminating two full-bore shutoff valves as well as the reduction from two vessel/ system connections to one provides additional cost benefits.

fig.2

The applicable standards, impositions, technical rules, and recommendations allow explicitly the use of change over valves when their design ensures that even during the switchover procedure the necessary free section for choke free flow is guaranteed. Phönix change over valves comply with this requirement. In addition the valves are designed for a high flow rate and minimal pressure drop.

For critical services involving toxic, aggressive or corrosive products that pose direct or indirect threats to people, plant, and environment the discharge into a closed collecting system might be required. For this purpose Phönix offers change over valve combinations to allow the mechanical link of two change over valves. One upstream and one downstream of the safety relief devices (fig. 3). The mechanical link allows operating both valves into the same direction and prevents involuntary isolation of the safety relief devices.

fig.3

Both the upstream and downstream change over valve must have identical dimensions in order to provide a synchronized controllable operation. Full lift safety relief valves have different inlet and outlet orifices. Therefore, pipe reducers must be placed between the upstream change over valve and the safety relief valves. This solution also allows for a very low pressure drop to the inlet of the safety relief valves and avoids expensive modifications of the change over valves.

To suit the nature of the process fluid, Phönix offers either bellows sealed or gland packed valves. Both options are part of the standard manufacturing program and can be equipped with manual, pneumatic, or electric operation. For fluids that tend to polymerize or crystallize the valves are available with optional heating jackets. For more information regarding design, standard materials, and options please refer to the product description of valve models 370 and 320.

Applications & design features

Applications

The 320 series is designed for dual relief valve systems to allow maintenance of the relief valves without the system being down, for reduction of vessel connections, for fast and easy operation, and for protection against involuntary isolation of both safety relief devices at the same time. For applications that require discharge into a collecting system model 320.1 provides a simple mechanism for the linkage of two change over valves for simultaneous operation.

Models 320 / 320.1 with a reliable, bubble tight shut-off can replace conventional three-way ball or plug valves. They are commonly used with non-hazardous media such as boiler and cooling water, saturated steam, and in similar systems as a bypass station to avoid shutdowns or as change over valve in combination with safety relief devices. Additionally, in polymer systems the change over valves are used to switch to start-up tanks for solvent flushing.

Design features

Body and bonnet

- split-body design allows for rotation of elbows to any 90° angle to accommodate different installation situation
- body bonnet joint gasket is fully confined to prevent gasket flow or blowout
- body parts are one-piece forgings or castings with larger than required wall thickness and integral flanges

Seats

- solid hardfacings for outstanding corrosion and wear resistance
- knife edge metal-to-metal seat for bubble-tight shutoff
- replaceable disc for inexpensive maintenance

Stem

- two-piece stem design eliminates stem bearings along with their maintenance needs
- cold-rolled and polished stem for reduced packing wear
- allows easy adaption for any type of actuation

= Zero emissions, zero seat leakage, low maintenance

Standard Materials of Construction

Options
